

## Chapter 2: Study Guide

Fill in the blanks as you study the chapter.

### 2.1 THE MEASURE OF SCIENCE

#### The Metric System

In the metric system, units of different sizes are related by \_\_\_\_\_. The initials \_\_\_\_\_ stand for the International System of Units. The three fundamental units measure the quantities \_\_\_\_\_, \_\_\_\_\_, and \_\_\_\_\_. The meter is the SI unit of \_\_\_\_\_. The second is the SI unit of \_\_\_\_\_. The kilogram is the SI unit of \_\_\_\_\_. Other units are called derived units because they are \_\_\_\_\_ of fundamental units.

#### Scientific Notation

Scientific notation is based on \_\_\_\_\_ notation. In scientific notation, a measurement is expressed as a number between \_\_\_\_\_ and \_\_\_\_\_ multiplied by a whole-number \_\_\_\_\_ of ten. When numbers are converted to scientific notation, the decimal point is moved until there is one \_\_\_\_\_ digit to the \_\_\_\_\_ of the decimal point. The number of places the decimal point is moved is used as the exponent of ten. If the decimal point is moved to the left, the exponent becomes larger. If the decimal point is moved to the right, the exponent becomes smaller.

#### Prefixes Used with SI Units

SI units are changed by powers of \_\_\_\_\_ by the use of prefixes. The prefix for one tenth is \_\_\_\_\_. The prefix for one thousandth is \_\_\_\_\_. The prefix that changes a unit by one thousand is \_\_\_\_\_. All metric units use \_\_\_\_\_ prefixes.

#### Arithmetic Operations in Scientific Notation

When numbers are in scientific notation, they may be added or subtracted if the numbers have the same \_\_\_\_\_. After the numbers are added, the exponent is \_\_\_\_\_. If the powers of ten are not the same, the \_\_\_\_\_ must be moved, and the \_\_\_\_\_ must be changed before the numbers can be added. For multiplying numbers in scientific notation, the \_\_\_\_\_ do not have to be the same. After the numbers are multiplied, the exponents are \_\_\_\_\_ and the units are \_\_\_\_\_.

## 2.2 NOT ALL IS CERTAIN

### Uncertainties of Measurements

A common source of error in making measurements comes from the \_\_\_\_\_ at which the instrument is read. Parallax is the apparent change in \_\_\_\_\_ of an object when it is seen from different \_\_\_\_\_. Reading instruments at \_\_\_\_\_ level and \_\_\_\_\_ reduces error due to parallax.

### Accuracy and Precision

Precision is the degree of \_\_\_\_\_ to which the measurement of a quantity can be \_\_\_\_\_. The precision of a measuring device is determined by the \_\_\_\_\_ division on its scale. Accuracy is the extent to which a measured value agrees with the \_\_\_\_\_ value of a quantity. Accuracy can be affected by changes in the \_\_\_\_\_ used to make the measurement. Uncertainties in measurement affect \_\_\_\_\_ but not \_\_\_\_\_.

### Significant Digits

In making measurements, there is a limit to the number of \_\_\_\_\_ that are valid. This limitation is caused by the \_\_\_\_\_ of the instrument used. The digits that are valid are called \_\_\_\_\_ digits. The last significant digit in a measurement is a(n) \_\_\_\_\_, so it is \_\_\_\_\_. All \_\_\_\_\_ digits are considered to be significant. All final zeros-the decimal point are significant. Zeroes between two other significant digits \_\_\_\_\_ significant. Zeros used for spacing between significant digits and the decimal point \_\_\_\_\_ significant.

### Operations Using Significant Digits

The result of a mathematical operation with measurements cannot be more precise than the \_\_\_\_\_ precise measurement. When numbers are added or subtracted, the operation is performed first, and the answer is rounded off to correspond to the \_\_\_\_\_ value involved. When numbers are multiplied or divided, the operation is performed first, and then the answer is rounded off to \_\_\_\_\_ number of significant digits as the factor with the-number of significant digits. Significant digits are used when calculating with \_\_\_\_\_, but not when \_\_\_\_\_.

## 2.3 DISPLAYING DATA

### Graphing Data

When data are analyzed, the variable that is \_\_\_\_\_ is the independent variable. The dependent variables are the \_\_\_\_\_ of the independent variable. The \_\_\_\_\_ variable is plotted on the horizontal axis and the \_\_\_\_\_ variable is plotted on the vertical axis. After the dependent and independent variables have been identified, the \_\_\_\_\_ of each variable must be determined. It must be determined if the \_\_\_\_\_ is a valid data point. Each axis should be \_\_\_\_\_ and \_\_\_\_\_. Then the \_\_\_\_\_ are plotted and the \_\_\_\_\_ is drawn. Finally, the graph should be given a(n) \_\_\_\_\_.

### Linear, Quadratic, and Inverse Relationships

The graph of a linear relationship is a(n) \_\_\_\_\_. The equation for such a relationship is \_\_\_\_\_. In this equation,  $m$  represents the \_\_\_\_\_ and  $b$  represents the \_\_\_\_\_. When one variable varies directly with the square of the other, the curve is in the shape of a(n) \_\_\_\_\_. The equation for such a curve is called a(n) \_\_\_\_\_ equation, and is written as \_\_\_\_\_. In this equation,  $k$  represents a(n) \_\_\_\_\_. In an inverse relationship, the curve is a(n) \_\_\_\_\_.

## 2.4 MANIPULATING EQUATIONS

### Solving Equations Using Algebra

In manipulating equations, the relationship must not be \_\_\_\_\_. If one side of the equation is divided by a variable, the other side of the equation should be \_\_\_\_\_ by that variable. Any operation performed on one side of the equation must be \_\_\_\_\_ the operation performed on the other side of the equation. If the equation for density,  $D = m/V$ , is solved for  $m$ , the correct equation is \_\_\_\_\_.

### Units in Equations

Before mathematical operations are carried out, all terms in the equation must have \_\_\_\_\_ units. When an answer is written, it must include both the numerical \_\_\_\_\_ and the \_\_\_\_\_. If a term has several units, they are treated like any other mathematical \_\_\_\_\_.
